Received 2 August 2011/Accepted 4 August 2011

We report the first whole-genome sequence of the Mycobacterium colombiense type strain, CECT 3035, which was initially isolated from Colombian HIV-positive patients and causes respiratory and disseminated infections. Preliminary comparative analyses indicate that the M. colombiense lineage has experienced a substantial genome expansion, possibly contributing to its distinct pathogenic capacity.

The genus Mycobacterium comprises nearly 150 species (2, 3), including a number of human pathogens that pose major challenges to public health. Mycobacterium colombiense is a slow-growing, urease-positive, nontuberculous mycobacterium (NTM) that belongs to the Mycobacterium avium complex (MAC). M. colombiense was originally isolated from HIV-positive individuals in Bogotá, Colombia, and the patient isolates were determined to represent a distinct species by virtue of sequence comparisons with closely related Mycobacterium species (7). Since the discovery of this new species in 2006, M. colombiense has been confirmed to cause respiratory disease and disseminated infection in immunocompromised HIV patients, as well as lymphadenopathy in immunocompetent children (1, 8). Nevertheless, very little is currently known about the molecular mechanisms that underlie M. colombiense infection and pathogenesis. We have characterized the complete genome sequence of M. colombiense in an effort to better understand its virulence mechanisms.

The M. colombiense genome was sequenced by a whole-genome shotgun strategy using Roche 454 GS-FLX titanium pyrosequencing technology. A total of 720,174 sequence reads were generated, with an average read length of 375 bp, yielding more than 270 Mb of total sequence. This represents 45× coverage for the estimated 5.6-Mb genome size. A de novo assembly of the 454 single-end data was created using the Newbler assembler (Roche), version 2.6, resulting in 27 large contigs with an N50 of 436 kb. Genome annotation was performed using the NCBI Prokaryotic Genomes Automatic Annotation Pipeline (PGAAP), which produces functional annotation using the NCBI nonredundant protein and protein cluster databases with functional domain assignments for each protein by RPS-BLAST (5) against the NCBI Conserved Domain Database (6). The M. colombiense genome was predicted to encode 5,230 coding sequences (CDS).

M. colombiense was previously shown to be most closely related to M. avium, based on 16S rRNA sequence analysis along with DNA-DNA hybridization experiments (7). Here, we show that M. colombiense is most closely related to M. avium subsp. paratuberculosis (4) and confirm these results via sequence comparisons of M. colombiense contigs against the NCBI microbial sequence database. Despite the close relationship between these two species, reference-based assembly of the M. colombiense genome using M. avium subsp. paratuberculosis produced a highly fragmented assembly, with markedly lower quality than seen for the de novo assembly (1,914 large contigs with an N50 of 1,253), indicating that numerous genome rearrangements have occurred since the two species diverged. Furthermore, our characterization of the M. colombiense genome shows it to be substantially larger (5.6 Mb) than the genome of M. avium (4.8 Mb) and to encode many more genes (5,230 versus 4,400). Sequence alignments between the two species revealed that these differences could be attributed to large genomic insertions specific to the M. colombiense lineage. We hypothesize that a genome expansion may have allowed for the elaboration of novel pathways that contribute to the virulence of this emerging opportunistic pathogen. Additional genomic and functional analyses are needed to interrogate this hypothesis.

Nucleotide sequence accession number. The M. colombiense Whole Genome Shotgun project has been deposited at DDBJ/EMBL/GenBank under the accession number AFVW00000000.

This work was supported by an Alfred P. Sloan Research Fellowship in Computational and Evolutionary Molecular Biology (BR-4839 to I.K.J.) and the NCBI Scientific Visitors Program (ORISE to M.G.-P.). The research was supported in part by the Intramural Research Program of the NIH, NLM, NCBI.

We thank the Spanish Type Culture Collection (CECT) for providing strains.
